Roll Stability Control (RSC) is an enhancement to the ABS system using additional inputs in conjunction with the controller to assist drivers in managing the conditions that may result in commercial vehicle rollovers. When RSC senses conditions that may result in a rollover, it reduces engine torque, engages the engine retarder, applies pressure to the drive axle brakes and trailer brakes to slow the vehicle down. RSC works automatically. The driver does not have to select this feature. Refer to Stability Control Systems Brochure for more information.

For DDC engine controls, Band 1 is the limit for lower transmission gears (e.g., gears 1 - 3 on a 9- or 10-speed transmission). Band 2 is the limit for mid-range transmission gears (e.g., gears 4 -7 on a 9-speed transmission). Band 3 is used for the transmission's highest one or two gears. MPH limits should be calculated using actual transmission gear ratios using the formula: MPH Limit for Band=(RPM Limit x 60) / (Tire Revs per Mile x Rear Axle Ratio x Transmission Gear Ratio). 4. For best vehicle performance, the RMP limit for Band 1 should be set lower than or equal to the RPM limit for Band 2. 5.
